Abstract

In this paper, we show that the class of representable residuated semigroups has the finite representation property. That is, every finite representable residuated semigroup is isomorphic to some algebra over a finite base. This result gives a positive solution to Problem 19.17 from the monograph by Hirsch and Hodkinson [16].

1 Introduction

Relation algebras are the kind of Boolean algebras with operators representing algebras of binary relations [23]. One often emphasise the following two classes of relation algebras. The first class called **RA** consists of algebras the signature of which is $\{0, 1, +, -, ;, \smile, \mathbf{1}'\}$ obeying the certain axioms that we define precisely below. The second class called **RRA**, the class of representable relation algebras, consists of algebras isomorphic to set relation algebras. **RRA** is a subclass of **RA**, but the converse inclusion does not hold. That is, there exist relation algebras having no representation as set relation algebras [26]. Moreover, the class **RRA** is not finitely axiomatisable in contrast to **RA** [29]. The problem of determining whether a given finite relation algebra is representable is undecidable, see [15].

Under these circumstances, one may conclude that relation algebras are quite badly behaved. The study of such reducts is mostly motivated by such “bad behaviour” in order to avoid these restrictions and determine the possible reasons for them.

There are several results on reducts of relation algebras having no finite axiomatisation such as ordered monoids [13], distributive residuated lattices [3], join semilattice-ordered semigroups [4], algebras whose signature contains composition, meet, and converse [21], etc.

On the other hand, such classes as representable residuated semigroups and monoids [3], and ordered domain algebras [18] are finitely axiomatisable. There are also plenty of subsignatures for which the question of finite axiomatisability remains open, see, e. g., [4].

The other direction we emphasise is related to finite representability. A finite algebra of relations has the finite representation property if it is isomorphic to some algebra of relations on a finite base. The investigation is of interest to study such aspects as the decidability of membership of $\mathbf{R}(\tau)$. The finite representation property also implies recursivity of the class of all finite representable τ -structures [12], if the whole class is finitely axiomatisable. Here, τ is a subsignature of operations definable in $\{0, 1, +, -, ;, \smile, \mathbf{1}'\}$. The examples of the class having the finite representation property are some classes of algebras [12] [18] [28], the subsignature of which contains the domain and range operators. The other kind of algebras of binary relations

having the finite representation property is semigroups with so-called demonic refinement has been recently studied by Hirsch and Šemrl [19].

Other algebras of relations such as weakly associative or relativised cylindric set algebras of a finite dimension have a similar property called the finite base property [2].

There are subsignatures of relation algebras τ such that the class $\mathbf{R}(\tau)$ of representable reducts fails to have the finite representation property. For instance, $\{;, \cdot\}$, see [27]. In general, (un)decidability of determining whether a finite relation algebra has a finite representation is an open question [16, Problem 18.18].

In this paper, we consider reducts of relation algebras the signature of which consists of composition, residuals, and the binary relation symbol denoting partial ordering, that is, the class of representable residuated semigroups. We show that $\mathbf{R}(;, \backslash, /, \leq)$ has the finite representation property. As result, Problem 19.17 of [16] has a positive solution. We also note that this result implies of membership decidability of $\mathbf{R}(;, \backslash, /, \leq)$ for finite structures and the class of finite representable residuated semigroups is recursive. The solution is surprisingly simple and based on the Dedekind-MacNeille completion and the relation representation of quantales. We consider a finite residuated semigroup and embed into a finite quantale mapping every element to its lower cone. After that, we apply the relational representation for quantales. As a result, the original finite residuated semigroup has a Zaretski-style representation [34] and this satisfies the finite base requirement.

2 Preliminaries

Let us the basic definitions related to relation algebras [16].

Definition 1. A relation algebra is an algebra $\mathcal{R} = \langle R, 0, 1, +, -, ;, \smile, \mathbf{1} \rangle$ such that $\langle R, 0, 1, +, - \rangle$ is a Boolean algebra and the following equations hold, for each $a, b, c \in R$:

1. $a; (b; c) = (a; b); c$,
2. $(a + b); c = (a; c) + (b; c)$,
3. $a; \mathbf{1}' = a$,
4. $a^{\smile\smile} = a$,
5. $(a + b)^{\smile} = a^{\smile} + b^{\smile}$,
6. $(a; b)^{\smile} = b^{\smile}; a^{\smile}$,
7. $a^{\smile}; -(a; b) \leq -b$.

Note that $a \leq b$ iff $a + b = b$ iff $a \cdot b = a$, where $a \cdot b = -(-a + -b)$. \mathbf{RA} is the class of all relation algebras.

Definition 2. A proper relation algebra (or, a set relation algebra) is an algebra $\mathcal{R} = \langle R, 0, 1, \cup, -, ;, \smile, \mathbf{1} \rangle$ such that $R \subseteq \mathcal{P}(W)$, where X is a base set, $W \subseteq X \times X$ is an equivalence relation, $0 = \emptyset$, $1 = W$, \cup and $-$ are set-theoretic union and complement respectively, $;$ is relation composition, \smile is relation converse, $\mathbf{1}'$ is the identity relation restricted to W , that is:

1. $a; b = \{\langle x, z \rangle \in W \mid \exists y \langle x, y \rangle \in a \ \& \ \langle y, z \rangle \in b\}$
2. $a^{\smile} = \{\langle x, y \rangle \in W \mid \langle y, x \rangle \in a\}$

$$3. \mathbf{1}' = \{\langle x, y \rangle \in W \mid x = y\}$$

PRA is the class of all proper relation algebras. **RRA** is the class of all representable relation algebras, that is, the closure of **PRA** under isomorphic copies.

We will use the following notation due to, for example, [17]. Let τ be a subset of operations and predicates definable in **RA**. $\mathbf{R}(\tau)$ is the class of subalgebras of τ -subreducts of algebras belonging to **RRA**. We assume that $\mathbf{R}(\tau)$ is closed under isomorphic copies.

A τ -structure is *representable* if it is isomorphic to some algebra of relations of τ -signature. A representable finite τ -structure has a *finite representation over a finite base* if it is isomorphic to some finite representable over a finite base. $\mathbf{R}(\tau)$ has the finite representation property if every $\mathcal{A} \in \mathbf{R}(\tau)$ has a finite representation over a finite base.

One may express residuals in every $\mathcal{R} \in \mathbf{RA}$ as follows using Boolean negation, inversion, and composition as follows:

$$1. a \backslash b = -(a^\smile; -b)$$

$$2. a / b = -(-a; b^\smile)$$

These residuals have the following explicit definition in $\mathcal{R} \in \mathbf{PRA}$:

$$1. a \backslash b = \{\langle x, y \rangle \mid \forall z (z, x) \in a \Rightarrow (z, y) \in b\}$$

$$2. a / b = \{\langle x, y \rangle \mid \forall z (y, z) \in b \Rightarrow (x, z) \in a\}$$

One may visualise residuals in **RRA** with the following triangles:

3 The case of residuated semigroups

The problem we are interested in is the following [16, Problem 19.17]:

Does $\mathbf{R}(\cdot, \cdot, \cdot, \cdot, \cdot, \cdot)$ have the finite representation property?

Let us introduce the notion of a residuated semigroup. Historically, residuated structures were introduced by Krull to study ideals of rings [24]. Structures of this kind have been considered further within semantic aspects of substructural logics, see, for example, [22].

Definition 3. A residuated semigroup is an algebra $\mathcal{A} = \langle A, \cdot, \cdot, \cdot, \cdot, \cdot \rangle$ such that $\langle A, \cdot, \cdot, \cdot, \cdot \rangle$ is a partially ordered residuated semigroup and $\cdot, /$ are binary operations satisfying the residuation property:

$$b \leq a \backslash c \Leftrightarrow a \cdot b \leq c \Leftrightarrow a \leq c / b$$

RS is the class of all residuated semigroups.

The class $\mathbf{R}(\cdot, \cdot, \cdot, \cdot, \cdot, \cdot)$ consists of the following structures:

Definition 4. Let A be a set of binary relations on some base set W such that $R = \cup A$ is transitive and W is a domain of R . A relation residuated semigroup is an algebra $\mathcal{A} = \langle A, \cdot, \cdot, \cdot, \cdot, \cdot \rangle$ where for each $a, b \in A$

1. $a; b = \{(x, z) \mid \exists y \in W ((x, y) \in a \ \& \ (y, z) \in b)\}$,
2. $a \backslash b = \{(x, y) \mid \forall z \in W ((z, x) \in a \Rightarrow (z, y) \in b)\}$,
3. $a / b = \{(x, y) \mid \forall z \in W ((y, z) \in b \Rightarrow (x, z) \in a)\}$,
4. $a \leq b$ iff $a \subseteq b$.

A residuated semigroup is called *representable* if it is isomorphic to some algebra belonging to $\mathbf{R}(\cdot, \cdot, \cdot, \cdot, \cdot, \cdot)$.

Definition 5. Let $\tau = \{\cdot, \cdot, \cdot, \cdot, \cdot, \cdot\}$, \mathcal{A} a τ -structure, and X a base set. An *interpretation* R over a base X maps every $a \in \mathcal{A}$ to a binary relation $a^R \subseteq X \times X$. A *representation* of \mathcal{A} is an interpretation R satisfying the following conditions:

1. $a \leq b$ iff $a^R \subseteq b^R$,
2. $(a; b)^R = \{(x, y) \mid \exists z \in X ((x, z) \in a^R \ \& \ (z, y) \in b^R)\} = a^R; b^R$,
3. $(a \backslash b)^R = \{(x, y) \mid \forall z \in X ((z, x) \in a^R \Rightarrow (z, y) \in b^R)\} = a^R \backslash b^R$,
4. $(a / b)^R = \{(x, y) \mid \forall z \in X ((y, z) \in a^R \Rightarrow (x, z) \in b^R)\} = a^R / b^R$.

Andréka and Mikulás proved the representation theorem for \mathbf{RS} ([3]) in the fashion of step-by-step representation. See this paper to learn more about step-by-step representations in general [14]. As it well known, the logic of such structures is the Lambek calculus [25], so we also have the relational completeness of the Lambek calculus.

This fact also claims that the theory of $\mathbf{R}(\cdot, \cdot, \cdot, \cdot, \cdot, \cdot)$ is finitely axiomatisable since their theories coincide, and the class of all residuated semigroup is finitely axiomatisable.

One may rephrase the result of the theorem by Andréka and Mikulás as \mathcal{A} is representable iff \mathcal{A} is a residuated semigroup, where \mathcal{A} is a structure of the signature $\{\cdot, \cdot, \cdot, \cdot, \cdot, \cdot\}$. Thus, it is sufficient to show that any finite residuated semigroup has a representation over a finite base in order to show that $\mathbf{R}(\cdot, \cdot, \cdot, \cdot, \cdot, \cdot)$ has the finite representation property.

Let us start with preliminary order-theoretic definitions. Recall that a *closure operator* on a poset $\langle P, \leq \rangle$ is a monotone map $j : P \rightarrow P$ satisfying $a \leq ja = jja$ for each $a \in P$. Given $a \in P$, a *lower cone* generated by a is a subset $\downarrow a = \{x \in P \mid x \leq a\}$.

A quantale is a complete lattice-ordered semigroup. Quantales has been initially introduced by Mulvey to provide a noncommutative generalisation of locales, study the spectra of C^* -algebras, and classify Penrose tilings, see [30] [31].

Definition 6. A *quantale* is a structure $\mathcal{Q} = \langle Q, \cdot, \cdot, \cdot, \cdot, \cdot \rangle$ such that $\mathcal{Q} = \langle Q, \cdot \rangle$ is a complete lattice, $\langle Q, \cdot \rangle$ is a semigroup, and the following conditions hold for each $a \in Q$ and $A \subseteq Q$:

1. $a; \Sigma A = \Sigma\{a; q \mid q \in A\}$,
2. $\Sigma A; a = \Sigma\{q; a \mid q \in A\}$.

Note that any quantale is a residuated semigroup as well. Given a quantale $\mathcal{Q} = \langle Q, \cdot, \cdot, \cdot, \cdot, \cdot \rangle$, One may express residuals uniquely with supremum and product as follows for each $a, b \in Q$:

1. $a \backslash b = \Sigma\{c \in Q \mid a; c \leq b\}$,
2. $a / b = \Sigma\{c \in Q \mid b; c \leq a\}$.

A quantic nucleus is a closure operator on a quantale allowing one to define subalgebras. Such an operator is a generalisation of a well-known nucleus operator in locale theory and pointfree topology, see, e. g., [5]. The following definition and the proposition below are due to [32, Theorem 3.1.1].

Definition 7. A *quantic nucleus* on a quantale $\langle A, ;, \Sigma \rangle$ is a mapping $j : A \rightarrow A$ such that j a closure operator satisfying $ja; jb \leq j(a; b)$.

Proposition 1. Let $\mathcal{A} = \langle A, ;, \Sigma \rangle$ be a quantale and j a quantic nucleus, then $\mathcal{A}_j = \{a \in A \mid ja = a\}$ forms a quantale, where $a;_j b = j(a; b)$ and $\Sigma_j A = j(\Sigma A)$ for each $a, b \in A_j$ and $A \subseteq \mathcal{A}_j$.

One may embed any residuated semigroup into some quantale with the Dedekind-MacNeille completion (see, for example, [33]) as follows. According to Goldblatt [11], residuated semigroups have the following representation based on quantic nuclei and the Galois connection.

We need this construction to solve the problem, let us discuss it briefly. See Goldblatt's paper to have a complete argument [11].

Let $\mathcal{A} = \langle A, \leq, ;, \backslash, / \rangle$ be a residuated semigroup. Then $\langle \mathcal{P}(A), ;, \bigcup \rangle$ is a quantale, where the product operation on subsets is defined with the pairwise products of their elements.

Let $X \subseteq A$. We put lX and uX as the sets of lower and upper bounds of X in A . We also put $mX = luX$. Note that the lower cone of an arbitrary x is m -closed, that is, $m(\downarrow x) = \downarrow x$.

$m : \mathcal{P}(A) \rightarrow \mathcal{P}(A)$ is a closure operator and the set

$$(\mathcal{P}(A))_m = \{X \in \mathcal{P}(A) \mid mX = X\}$$

forms a complete lattice with $\Sigma_m \mathcal{X} = m(\bigcup \mathcal{X})$ and $\Pi_m = \bigcap \mathcal{X}$ [9].

The key observation is that m is a quantic nucleus on $\mathcal{P}(A)$, that is, $mA; mB \subseteq m(A; B)$. We refer here to the Goldblatt's paper mentioned above.

Thus, according to Proposition 1, $\langle (\mathcal{P}(A))_m, \subseteq, ;_m \rangle$ is a quantale itself since m is a quantic nucleus.

Let us define a mapping $f_m : \mathcal{A} \rightarrow (\mathcal{P}(A))_m$ such that $f_m : a \mapsto \downarrow a$. This map is well-defined since any lower cone generated by a point is m -closed. Moreover, f_m preserves products, residuals, and existing suprema. In particular, f_m is a residuated semigroup embedding.

As a result, we have the following representation theorem.

Theorem 1. Every residuated semigroup has an isomorphic embedding to the subalgebra of some quantale.

In their turn, quantales have a relational representation. First of all, let us define a relational quantale. The notion of a relational quantale was introduced by Brown and Gurr to represent quantales as algebras of relations and study relational semantics of the full Lambek calculus, the logic of bounded residuated lattices, see, e.g., [6].

Definition 8. Let A be a non-empty set. A *relational quantale* on A is an algebra $\langle R, \subseteq, ; \rangle$, where

1. $R \subseteq \mathcal{P}(A \times A)$,
2. $\langle R, \subseteq \rangle$ is a complete join-semilattice,
3. $;$ is a relational composition that respects all suprema in both coordinates.

The uniqueness of residuals in any quantale implies the following quite obvious fact.

Proposition 2. *Let \mathcal{A} be a relational quantale over a base set X , then for each $a, b \in \mathcal{A}$*

1. $a \backslash b = \{(x, y) \in X^2 \mid \forall z \in X ((z, x) \in a \Rightarrow (z, y) \in b)\},$
2. $a / b = \{(x, y) \in X^2 \mid \forall z \in X ((y, z) \in b \Rightarrow (x, z) \in a)\}.$

Let us discuss the relational representation of quantales. This construction is due to Brown and Gurr [6].

Let \mathcal{Q} be a quantale and $\mathcal{G}(\mathcal{Q})$ a set of its generators. We define:

$$\hat{a} = \{\langle g, q \rangle \mid g \in \mathcal{G}(\mathcal{Q}), q \in \mathcal{Q}, g \leq a; q\} \quad \hat{\mathcal{Q}} = \{\hat{a} \mid a \in \mathcal{Q}\}$$

The mapping $a \mapsto \hat{a}$ satisfies the following conditions:

1. $a \leq b$ iff $\hat{a} \subseteq \hat{b}$,
2. $\widehat{\Sigma A} = \Sigma \hat{A}$, $\hat{a}; \hat{b} = \widehat{a; b}$, and $\langle \hat{\mathcal{Q}}, \subseteq, \Sigma \rangle$ is a complete lattice,
3. $\langle \hat{\mathcal{Q}}, \subseteq, ; \rangle$ is a relational quantale,
4. \mathcal{Q} is isomorphic to $\langle \hat{\mathcal{Q}}, \subseteq, ; \rangle$,
5. $a \mapsto \hat{a}$ is a quantale isomorphism.

Theorem 2. *Every quantale $\mathcal{Q} = \langle \mathcal{Q}, ;, \Sigma \rangle$ is isomorphic to a relational quantale on \mathcal{Q} as a base set.*

We describe how we use Theorem 1, Proposition 2, and Theorem 2 and constructions from their proofs to obtain an interpretation of the signature of residuated semigroups on $\mathbf{R}(\cdot, \backslash, /, \leq)$.

Let \mathcal{A} be a residuated semigroup and $\mathcal{Q}_{\mathcal{A}}$ is a quantale of Galois closed subsets of \mathcal{A} . $\widehat{\mathcal{Q}_{\mathcal{A}}}$ is the corresponding relational quantale. Let us define an interpretation $R : \mathcal{A} \rightarrow \widehat{\mathcal{Q}_{\mathcal{A}}}$ such that

$$R : a \mapsto a^R = \downarrow a$$

According to the lemma below, such an interpretation is a representation. As we have already said above, the mapping $a \mapsto \downarrow a$ is order-preserving. Moreover, this mapping commutes with products and residuals.

Lemma 1. *Let τ be a signature of residuated semigroups. An interpretation $R : \mathcal{A} \rightarrow \widehat{\mathcal{Q}_{\mathcal{A}}}$ such that $R : a \mapsto a^R = \downarrow a$ is a τ -representation.*

Proof. By Theorem 1, $\mathcal{Q}_{\mathcal{A}}$ is isomorphic to $\widehat{\mathcal{Q}_{\mathcal{A}}}$. The isomorphism is established with the mapping $\downarrow a \mapsto \widehat{\downarrow a}$ according to Theorem 2. Residuals in $\widehat{\mathcal{Q}_{\mathcal{A}}}$ are well-defined by Proposition 2. \square

Theorem 1, Theorem 2, and the lemma above imply the following statement.

Corollary 1. *Every residuated semigroup is isomorphic to the subalgebra of some relational quantale.*

In particular, the representation we proposed implies the solution to [16, Problem 19.17].

Theorem 3. $\mathbf{R}(\cdot, \backslash, /, \leq)$ has the finite representation property.

Proof.

Let \mathcal{A} be a finite residuated semigroup.

The representation of \mathcal{A} as a subalgebra of a relational quantale clearly belongs to $\mathbf{R}(\cdot, \cdot, \cdot, \cdot, \cdot)$. This representation has the form

$$\widehat{\mathcal{A}} = \langle \{\downarrow a\}_{a \in \mathcal{A}}, \cdot, \cdot, \cdot, \cdot \rangle.$$

Moreover, such a representation with the corresponding relational quantale has the finite base, if the original algebra is finite. The base set of the quantale $\widehat{\mathcal{Q}}_{\mathcal{A}}$ is the set of Galois stable subsets of \mathcal{A} , the cardinality of which is finite. \square

The main corollary of Theorem 3 is that the Lambek calculus has the finite model property. Thus, we have a semantical proof of decidability of the Lambek calculus. Before that, there were several algebraic proofs that the Lambek calculus has the FMP [7], but the authors used to consider arbitrary algebras, not representable ones. Alternatively, one may show that the Lambek calculus is decidable syntactically, that is, via cut elimination and the subformula property [25].

Corollary 2. *The Lambek calculus is complete w.r.t finite relational models (has the FMP).*

Moreover, finite axiomatisability and having the finite representation property of $\mathbf{R}(\cdot, \cdot, \cdot, \cdot, \cdot)$ imply that the membership of $\mathbf{R}(\tau)_{fin}$ is decidable.

4 The case of join semilattice-ordered semigroups

A *join semilattice-ordered semigroup* is an algebra $\mathcal{A} = \langle A, \cdot, + \rangle$ such that $\langle A, \cdot \rangle$ is a semigroup, $\langle A, + \rangle$ is a join semilattice, and the following identity holds for all $a, b, c \in A$ the identity $a; (b + c) = a; b + a; c$ holds.

Let \mathcal{A} be a join semilattice-ordered semigroup and $X, Y \subseteq \mathcal{A}$, then $X; Y = \{x; y \mid x \in X, y \in Y\}$.

Let $\langle P, \leq \rangle$ be a partial order. An upper cone generated by x is the set $\uparrow x = \{a \in P \mid x \leq a\}$. Let $A \subseteq P$, then $\uparrow A = \bigcup_{x \in A} \uparrow x = \{a \in P \mid \exists x \in A, x \leq a\}$. The set of all upper cones of a poset $\langle P, \leq \rangle$ is denoted as $\text{Up}(P)$.

4.1 Axiomatising $\mathbf{R}(+, \cdot)$

Definition 9. A *representation* R of a join semilattice-ordered semigroup \mathcal{A} is an injection $R : \mathcal{A} \rightarrow 2^{D \times D}$ (where D is a non-empty base set) such that

1. $(a + b)^R = a^R \cup b^R$
2. $(a; b)^R = a^R \cdot b^R$

It is known that the class of all representable join-semilattice ordered semigroups has no finite axiomatisation [1]. This proof has been reproduced in [4] as well.

Definition 10. Let \mathcal{A} be a join-semilattice ordered semigroup. A *prenetwork* over \mathcal{A} is a pair (E, V, N) , where E is a set of nodes, V is a set of nodes such that $\langle E, V \rangle$ is a complete directed graph, and N is a function $l : V \rightarrow \text{Up}(\mathcal{A})$.

A prenetwork over \mathcal{A} is a network if the following hold:

1. For every $u, v \in E$ and for every $x, y, z \in \mathcal{A}$ $z \in l(u, v)$ and $z \leq x; y$ implies $x \in N(u, w)$ and $y \in l(w, v)$ for some $w \in E$.

2. For every $u, v, w \in E$ one has $l(u, v); l(v, w) \subseteq l(u, w)$.
3. For every $u, v \in E$ $l(u, v)$ is join-prime. That is, for each $a, b \in \mathcal{A}$ if $a + b \in l(u, v)$, then either $a \in l(u, v)$ or $b \in l(u, v)$.

Let $\mathcal{N}_1 = (E_1, V_1, l_1)$ and $\mathcal{N}_2 = (E_2, V_2, l_2)$ be (pre)networks, then \mathcal{N}_1 is a *subnetwork* of \mathcal{N}_2 , written as $\mathcal{N}_1 \subseteq \mathcal{N}_2$, if $E_1 \subseteq E_2$, $V_1 \subseteq V_2$, and for all $x, y \in E_1$ if $a \in l_1(x, y)$ then there is $b \in l_2(x, y)$ with $b \leq a$.

A \mathcal{N}_1 is an *induced* sub(pre)network of \mathcal{N}_2 , if $E_1 \subseteq E_2$ and for all $x, y \in E_1$ one has $l_1(x, y) = l_2(x, y)$.

Let $\{\mathcal{N}_i\}_{i \in I}$ be an indexed set of prenetworks (where each $\mathcal{N}_i = (E_i, V_i, l_i)$), then $\mathcal{N} = \bigcup_{i \in I} \mathcal{N}_i$ defined as (E, V, l)

1. $E = \bigcup_{i \in I} E_i$ and $V = \bigcup_{i \in I} V_i$
2. $l(x, y) = \bigcup_{i \in I} l_i(x, y)$ for each $x, y \in E$

Definition 11. Let $n \leq \omega$ and \mathcal{A} a join semilattice-ordered semigroup. A game $\mathcal{G}_n(\mathcal{A})$ has n rounds and consists of n finitary networks.

1. Round 0: \forall picks elements $a, b \in \mathcal{A}$ with $a \not\leq b$. \exists responds with a prenetwork $\mathcal{N}_0 = (E_0 = \{x_0, x_1\}, V_0 = \{(x_0, x_1)\}, l_0)$ such that $l_0(x_0, x_1) = \uparrow b$.
2. Round $n + 1$. Suppose, the prenetwork $\mathcal{N}_n = (E_n, V_n, l_n)$ has been played.

\forall has the following three options:

- (a) (**Composition move**): \forall can pick $x, y, z \in E_n$ with $a \in l_n(x, y)$ and $b \in l_n(y, z)$. We denote such a move as $N(x, y, z, a, b)$. Then \exists responds with $\mathcal{N}_{n+1} = (E_{n+1}, V_{n+1}, l_{n+1})$ such that \mathcal{N}_{n+1} is the same as \mathcal{N}_n , but $l_{n+1}(x, z) = \uparrow (l_n(x, y) \cup \{a; b\})$.

- (b) (**Witness move**):

\forall picks nodes $x, y \in E_n$ and $a, b \in \mathcal{A}$ such that $c \leq a; b$ for $c \in l_n(x, y)$. \exists has to find a witness. She responds with a fresh node z . We define the prenetwork T , the edges of which are x, y, z with the following labelling:

- i. $l_T(x, z) = \uparrow a$
- ii. $l_T(z, y) = \uparrow b$

For her response, \exists plays $\mathcal{N}_{n+1} = \mathcal{N}_n \cup T$

- (c) (**Join move**):

\forall picks nodes $x, y \in E_n$ and $a + b$ for $a, b \in \mathcal{A}$. \exists has the following two alternatives for her response:

- i. \exists chooses a and responds with the prenetwork $\mathcal{N}_{n+1} = \langle E_n, V_n, l_{n+1} \rangle$, where $l_{n+1}(x, y) = \uparrow (l_n(x, y) \cup \{a\})$.
- ii. \exists chooses b . The response is similar but $l_{n+1}(x, y) = \uparrow (l_n(x, y) \cup \{b\})$.

\exists wins for the match of the game $\mathcal{G}_n(\mathcal{A})$ if for each $0 \leq i \leq n$ \mathcal{N}_i is a network. \exists has a winning strategy, if she can win all the matches. Otherwise, \forall wins the game.

Lemma 2. Let \mathcal{A} be a join semilattice-ordered semigroup,

1. If \mathcal{A} is representable then \exists has a winning strategy in $\mathcal{G}_\omega(\mathcal{A})$.

2. If \mathcal{A} is infinite and \exists has a winning strategy in $\mathcal{G}_\omega(\mathcal{A})$ then \mathcal{A} is representable.
3. If \mathcal{A} is infinite and \forall has a winning strategy in $\mathcal{G}_\omega(\mathcal{A})$ then \mathcal{A} is not representable.

Proof.

1. Let h be a representation of \mathcal{A} over some domain D . \forall picks (a, b) with $a \not\leq b$ for the initial round. Let $\mathcal{N} = \langle E, V, l \rangle$ be a network being played. To win the game \exists maintains a map $\iota : E \rightarrow D$ such that $(\iota(x_0), \iota(x_1)) \in h(b) \setminus h(a)$ and for each $x, y \in E$ and $a \in l_{\mathcal{N}}(x, y)$ one has $(\iota(x), \iota(y)) \in h(a)$. The argument repeats the proof of the first item of [13, Proposition 5].

2. Firstly, let us suppose that $|\mathcal{A}| = \omega$.

Let $a, b \in \mathcal{A}$ such that $a \not\leq b$. We consider a play of the game where \forall pick the pair (a, b) in the initial round and plays $(\mathcal{N}, x, y, z, c, d)$ in the further rounds for each $x, y, z \in \text{Nodes}(\mathcal{N})$ and $c, d \in \mathcal{A}$. Here, $c \in l_{\mathcal{N}}(x, y)$ and $d \in l_{\mathcal{N}}(y, z)$.

\forall also plays all rounds $(\mathcal{N}, x, y, c, d)$ for each $x, y \in \text{Nodes}(\mathcal{N})$ and $c, d \in \mathcal{A}$ such that there is $e \in \mathcal{A}$ such that $e \leq c; d$ and $e \in l_{\mathcal{N}}(x, y)$.

\forall picks also $c + d$ and vertices $x, y \in \text{Nodes}(\mathcal{N})$ for $c, d \in \mathcal{A}$.

We have the following play of a game that we define as a sequence of prenetworks where \exists has a winning strategy for each $i < \omega$:

$$\mathcal{N}_0 \subseteq \mathcal{N}_1 \subseteq \mathcal{N}_2 \dots$$

Let us put $\mathcal{N}^*(a, b) = \bigcup_{i < \omega} \mathcal{N}_i$. It is clear that \mathcal{N}^* is a network.

Let us put the following network:

$$\mathcal{N} = \bigcup_{\substack{a, b \in \mathcal{A} \\ a \not\leq b}} \mathcal{N}^*(a, b)$$

\mathcal{N} is really a network since it is the disjoint union of networks.

The labelling function $l_{\mathcal{N}}$ respects $;$. Here, the argument is similar to the proof of [13, Proposition 5].

Let us define the $rep : \mathcal{A} \rightarrow \text{Nodes}(\mathcal{N})$:

$$rep(a) = \{(x, y) \mid \exists b \in \downarrow a \ b \in l_{\mathcal{N}}(x, y)\}$$

Let us ensure that rep is a representation.

- Let us show that $rep(a + b) = rep(a) \cup rep(b)$

Suppose $(x, y) \in rep(a + b)$. That is, there exists $c \leq a + b$ with $c \in l_{\mathcal{N}}(x, y)$, so does $a + b$ since $l_{\mathcal{N}}$ is an upper cone.

$a + b \in l_{\mathcal{N}}(x, y)$, that is,

$$a + b \in \bigcup_{\substack{a_1, a_0 \in \mathcal{A} \\ a_1 \not\leq a_0}} l_{\mathcal{N}^*(a_1, a_0)}(x, y)$$

That is, there are $a_1, a_0 \in \mathcal{A}$ with $a_1 \not\leq a_0$ such that $a + b \in l_{\mathcal{N}*}(a_1, a_0)(x, y)$. This means $a + b \in \bigcup_{i < \omega} \mathcal{N}_i$. \forall makes all possible join moves, so either $a \in l_{\mathcal{N}_{i+1}}(x, y)$ or $b \in l_{\mathcal{N}_{i+1}}(x, y)$ depending on what \exists chooses. Thus, $(x, y) \in \text{rep}(a) \cup \text{rep}(b)$.

Suppose for the converse, $(x, y) \in \text{rep}(a)$. We need $(x, y) \in \text{rep}(a + b)$. In other words, we have some $c \in \mathcal{A}$ with $c \leq a$ and $c \in l_{\mathcal{N}}(x, y)$. We have $c \leq a \leq a + b$, so $(x, y) \in \text{rep}(a + b)$.

- Let us show that $\text{rep}(a; b) = \text{rep}(a); \text{rep}(b)$.

Suppose $(x, y) \in \text{rep}(a; b)$. We need some z with $(x, z) \in \text{rep}(a)$ and $(z, y) \in \text{rep}(b)$.

There is $c \leq a; b$ with $c \in l_{\mathcal{N}}(x, y)$. That is, there are $a_1, a_0 \in \mathcal{A}$ and \mathcal{N}_i such that $c \in l_{\mathcal{N}_i}(x, y)$ where \forall plays (a_1, a_0) for the initial round.

By the condition, \forall makes the witness moves and \exists responds with a witness. Her response is a fresh node z such that $l_{\mathcal{N}_{i+1}}(x, z) = \uparrow(l_{\mathcal{N}_i}(x, z) \cup \{a\})$ and $l_{\mathcal{N}_{i+1}}(z, y) = \uparrow(l_{\mathcal{N}_i}(z, y) \cup \{b\})$. The inclusion $\text{rep}(a; b) \subseteq \text{rep}(a); \text{rep}(b)$ holds since all witness moves have been played and for every such a move there exists a witness.

- Suppose $(x, y) \in \text{rep}(a); \text{rep}(b)$. We need $(x, y) \in \text{rep}(a; b)$. That is, there exists $z \in \text{Nodes}(\mathcal{N})$ with $(x, z) \in \text{rep}(a)$ and $(z, y) \in \text{rep}(b)$. So, there are c, d such that $c \leq a$ with $c \in l_{\mathcal{N}}(x, z)$ and $d \leq b$ with $d \in l_{\mathcal{N}}(z, y)$. We also know that $l_{\mathcal{N}}(x, z); l_{\mathcal{N}}(z, y) \subseteq l_{\mathcal{N}}(x, y)$ because all composition moves have been played. So $c; d \in l_{\mathcal{N}}(x, y)$. That makes $(x, y) \in \text{rep}(a; b)$ since $c; d \leq a; b$.
- Injectivity: TODO

Now let us assume that $|\mathcal{A}| \geq \aleph_1$. By Tarski-Vaught theorem on elementary chain union (see [20, Theorem 2.5.2])

3.

□

The following proposition is a version of [16, Proposition 7.24] and the right-to-left part is proved using König's lemma [20, Exercise 5.6.3].

Proposition 3. *Let \mathcal{A} be a join semilattice-ordered semigroup, then there exists a game such that \mathcal{A} is representable iff \exists has a winning strategy in the all finite length games.*

Now we are seeking to obtain the explicit axiomatisation of $\mathbf{R}(\cdot, +)$. See [16, Chapter 9] for the discussion in detail to have a more general methodology. Our purpose is to provide the recursively enumerable axiomatisation of $\mathbf{R}(\cdot, +)$. Thus, according to famous Craig's trick [8], $\mathbf{R}(\cdot, +)$ will have the decidable axiomatisation. According to the proposition above, it is sufficient to extract the axioms claiming that \exists has a winning strategy in all finitary games.

Definition 12. Let $V = \{v_0, v_1, \dots\}$ be a countable set of variables. The set of terms T is generated by the following grammar:

$$T ::= V \mid (T + T) \mid (T; T)$$

Let us define the equivalence relation \approx on T as follows for t_1 and t_2 are terms:

$$t_1 \approx t_2 \text{ iff } \theta(t_1) = \theta(t_2) \text{ for each interpretation of variables in } \theta : V \rightarrow F(\omega).$$

where $F(\omega)$ is the free countably generated algebra of the variety of all join semilattice-ordered group semigroup. We have the following partial order on the T defined as

$$t_1 \leq t_2 \text{ iff } t_1 + t_2 \approx t_2, \text{ that is, } F(\omega) \models t_1 + t_2 = t_2$$

A subset $A \subseteq T$ of terms is called upward closed if for every term $t \in A$ one has $\uparrow t \subseteq A$, where $\uparrow t = \{t_1 \in T \mid t \leq t_1\}$.

Definition 13. A term network is a graph $\langle E, V, l \rangle$, where $\langle E, V \rangle$ is a complete directed graph and $l : V \rightarrow \text{Up}(F(\omega), \leq)$ is a labelling function.

Let \mathcal{A} be a join semilattice-ordered semigroup and $\vartheta : V \rightarrow \underline{\mathcal{A}}$ a valuation. The value of complex terms is defined inductively for $a, b \in T$:

1. $(a; b)^\vartheta = a^\vartheta; b^\vartheta$
2. $(a + b)^\vartheta = a^\vartheta + b^\vartheta$

Let $\mathcal{N} = \langle E, V, l \rangle$ a term network, \mathcal{A} be a join-semilattice ordered semigroup and $\vartheta : V \rightarrow \underline{\mathcal{A}}$ a valuation. Let us define the prenetwork \mathcal{N}^ϑ with the same edges and vertices with labelling $l^\vartheta(x, y) = \{t^\vartheta \mid t \in l_{\mathcal{N}}(x, y)\}$.

Let us ensure that \mathcal{N}^ϑ is well-defined. Let us consider ϑ as a homomorphism $F(\omega) \rightarrow \mathcal{A}$. We would like to know whether $\uparrow t^\vartheta \subseteq l^\vartheta(x, y)$ for $t^\vartheta \in l^\vartheta(x, y)$. So $t \in l(x, y)$. Suppose $t \leq t_1$, then t_1 clearly belongs to $l(x, y)$. So $l^\vartheta(x, y)$ is upward closed by the construction.

Let \mathcal{N} be a term network. We define the following three extensions of \mathcal{N} reflecting the composition, witness, and join moves respectively:

1. Let $x, y \in \text{Nodes}(\mathcal{N})$ and t a term. \mathcal{N}_c is the extension of \mathcal{N} , where $\text{Nodes}(\mathcal{N}_c) = \text{Nodes}(\mathcal{N})$ and $l_{\mathcal{N}}(x, y) \cup \uparrow t$ and $l_{\mathcal{N}_c}(u, v) = l_{\mathcal{N}}(u, v)$ for each $u \neq x$ and $v \neq y$. We denote this network as $\mathcal{N}_c(\mathcal{N}, x, y, t)$.
2. Let $x, y \in \text{Nodes}(\mathcal{N})$, z a fresh node, and t_1, t_2 any terms. Let us define a network T such that $\text{Nodes}(T) = \{x, y, z\}$. We define labelling as $l_T(x, y) = \uparrow t_1$ and $l_T(y, z) = \uparrow t_2$. So we put $\mathcal{N}_w = \mathcal{N} \cup T$. We denote this network as $\mathcal{N}_w(\mathcal{N}, x, y, z, t_1, t_2)$.
3. Let $x, y \in \text{Nodes}(\mathcal{N})$ and let t_1, t_2 be terms. Let us define $T_i = \langle \{x, y\}, \{(x, y)\}, l_{T_i} \rangle$, where $l_{T_i}(x, y) = \uparrow (l_{\mathcal{N}}(x, y) \cup t_i)$ for $i = 1, 2$. So $\mathcal{N}_{j_1} = \mathcal{N} \cup T_1$ and $\mathcal{N}_{j_2} = \mathcal{N} \cup T_2$. We denote this as $\mathcal{N}_j(\mathcal{N}, x, y, t_1, t_2)$.

Lemma 3. *For each $n < \omega$ there exists a first-order sentence σ_n such that \exists has a winning strategy in $\mathcal{G}_n(\mathcal{A})$ iff $\mathcal{A} \models \sigma_n$.*

Proof. As usual, for each $n < \omega$ we construct a formula σ_n claiming that \exists has a winning strategy in the game of length n . To be more precise, our purpose is to have

$$\exists \text{ has a winning strategy in } \mathcal{G}_n(\mathcal{N}^\vartheta, \mathcal{A}, \vartheta(v)) \text{ if and only if } \mathcal{A} \models \sigma_n(\mathcal{N}, v)$$

where \mathcal{A} is a join semilattice-ordered semigroup and $\vartheta : V \rightarrow \mathcal{A}$ is a variable assignment.

We define the sequence of formulas $\{\sigma_n\}_{n < \omega}$ recursively:

$$1. \sigma_0(\mathcal{N}, v) = \bigwedge_{a \in l_{\mathcal{N}}(x, y)} \neg(a \leq v)$$

This formula merely claims that \exists has a winning strategy in the zero length game.

2. Suppose $\sigma_n(\mathcal{N}, v)$ for $n < \omega$. Let us define a formula σ_{n+1} claiming that \exists always has a proper response for a network \mathcal{N} being played (which is defined by $\sigma_n(\mathcal{N}, v)$).

$\sigma_{n+1}(\mathcal{N}, v)$ is defined as follows:

$$\sigma_{n+1}(\mathcal{N}, v) = \sigma_{n+1_c}(\mathcal{N}, v) \wedge \sigma_{n+1_w}(\mathcal{N}, v) \wedge \sigma_{n+1_j}(\mathcal{N}, v)$$

where

$$\begin{aligned} \bullet \sigma_{n+1_c}(\mathcal{N}, v) &= \bigwedge_{x, y, z \in \text{Nodes}(\mathcal{N}), t_1 \in l_{\mathcal{N}}(x, y), t_2 \in l_{\mathcal{N}}(y, z)} \sigma_n(\mathcal{N}_c(x, z, t_1, t_2), v) \\ \bullet \sigma_{n+1_w}(\mathcal{N}, v) &= \bigwedge_{x, y \in \text{Nodes}(\mathcal{N}), t \in l_{\mathcal{N}}(x, y)} \forall u_1, u_2 (t \leq u_1; u_2 \rightarrow \bigvee \mathcal{N}_c(x, y, z, t_1, t_2)), \text{ where} \\ &\quad z \text{ is a fresh node.} \\ \bullet \sigma_{n+1_j}(\mathcal{N}, v) &= \bigwedge_{x, y \in \text{Nodes}(\mathcal{N})} \sigma_n(\mathcal{N}_{j_1}(\mathcal{N}, x, y, t_1, t_2), v) \vee \sigma_n(\mathcal{N}_{j_2}(\mathcal{N}, x, y, t_1, t_2), v) \end{aligned}$$

So, \exists has a winning strategy iff these formulas are true under the valuation ϑ since the formulas $\{\sigma_n\}_{n < \omega}$ encode the presence of a winning strategy for \exists on every finite round. \square

This inductive sequence of formulas provides us the explicit axiomatisation of the class of representable join semilattice-ordered semigroups.

Theorem 4. $\mathbf{R}(+, ;)$ is axiomatised with the axioms of join semilattice-ordered semigroups and the countable sequences of universal formulas $\{\rho_n\}_{n < \omega}$. Moreover, $\mathbf{R}(+, ;)$ has a recursively enumerable axiomatisation.

Proof. Being the class of **RRA**-reducts, $\mathbf{R}(+, ;)$ forms a pseudo-elementary class (see [10] to have a rigorous definition). So we apply [16, Theorem 9.28]. Therefore, a join semilattice-ordered semigroup \mathcal{A} is representable iff $\mathcal{A} \models \{\sigma_n\}_{n < \omega}$. Every σ_n for $n < \omega$ defined in the proof of Lemma 3 is equivalent to the universal formula ρ_n by bringing all universal quantifiers into the prefix of σ_n . \square

4.2 The finite representation property for $\mathbf{R}(+, ;)$

Theorem 5. $\mathbf{R}(+, ;)$ has the finite representation property.

Proof. Let $\mathcal{A} \in \mathbf{R}(+, ;)$ such that $|\mathcal{A}| < \omega$ and h a representation of \mathcal{A} . monkahmm □

The following corollary follows from finite representability and finite axiomatisability.

Corollary 3. The class $\mathbf{R}_{fin}(+, ;) = \{\mathcal{A} \in \mathbf{R}(+, ;) \mid |\mathcal{A}| < \omega\}$ is recursive. That is, the problem of membership for this class is decidable.

Proof. Let \mathcal{A} be a finite semilattice-ordered semigroup. We check axioms with the algorithm that yields “no”, if \mathcal{A} is not representable. So, in parallel, we check whether \mathcal{A} has a finite representation. If there exists such $n < \omega$ such that \mathcal{A} is representable over size n . Both sets are domains of corresponding computable functions, so they are enumerable. That makes $\mathbf{R}_{fin}(+, ;)$ decidable by Post’s theorem. □
