# The finite base property for some relation algebras subreducts

Daniel Rogozin

## 1 The Relation Algebras Background

We describe the basic definitions and results about relation algebras [9] [16].

#### Definition 1.

- 1. A relation algebra is an algebra  $\mathcal{R} = \langle R, 0, 1, \wedge, \vee, \neg, ;, \smile, \mathbf{1} \rangle$  such that  $\langle R, 0, 1, \wedge, \vee, \neg \rangle$  is a Boolean algebra and the following equations hold, for each  $a, b, c \in R$ :
  - (a) a;(b;c) = (a;b);c
  - (b)  $(a \lor b); c = (a; c) \lor (b; c)$
  - (c) a; 1 = a
  - (d)  $a^{\smile} = a$
  - (e)  $(a \lor b)^{\smile} = a^{\smile} \lor b^{\smile}$
  - $(f) (a;b)^{\smile} = b^{\smile}; a^{\smile}$
  - $(g) \ a^{\smile}; (\neg(a;b)) \leqslant \neg b$

where  $a \leq b$  iff  $a \wedge b = a$  iff  $a \vee b = b$ . **RA** denotes the class of all relation algebras.

- 2. A proper relation algebra is an algebra  $\mathcal{R} = \langle R, 0, 1, \wedge, \vee, \neg, ;, \check{\ }, \mathbf{1} \rangle$  such that  $R \subseteq \mathcal{P}(W)$ , where W is an equivalence relation;  $0 = \emptyset$ ; 1 = W;  $\wedge$ ,  $\vee$ ,  $\neg$  are set-theoretic intersection, union, and complement respectively; ; is relation composition,  $\check{\ }$  is relation converse,  $\mathbf{1}$  is a diagonal relation restricted to W, that is:
  - (a)  $a; b = \{\langle x, z \rangle \mid \exists y \langle x, y \rangle \in a \& \langle y, z \rangle \in b\}$
  - (b)  $a = \{\langle x, y \rangle \mid \langle y, x \rangle \in a\}$
  - (c)  $\mathbf{1} = \{\langle x, y \rangle \mid x = y\}$

The class of all proper relation algebras is denoted as  $\mathbf{PRA}$ . Rs is the class of all relation set algebras, proper relation algebra with a diagonal subrelation as an identity.  $\mathbf{RRA}$  is the class of all representable relation algebras, that is, the closure of  $\mathbf{PRA}$  under isomorphic copies. That is,  $\mathbf{RRA} = \mathbf{IPRA}$ .

Note that the (quasi)equational theories of those classes coincide, that is

$$\mathbf{IPRA} = \mathbf{RRA} = \mathbf{SPRs}$$

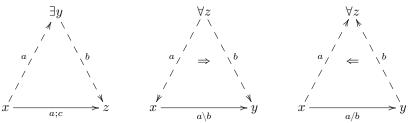

One may express residuals in every  $\mathcal{R} \in \mathbf{RA}$  as follows, for every  $a, b \in \mathcal{R}$ :

- 1.  $a \setminus b = \neg(a \smile; \neg b)$
- 2.  $a/b = \neg(\neg a; b)$

Those residuals have the following interpretation in  $\mathcal{R} \in \mathbf{PRA}$  (as well as in  $\mathbf{RRA}$ ), for every  $a, b \in \mathcal{R}$ :

- 1.  $a \setminus b = \{ \langle x, y \rangle \mid \forall z (z, x) \in a \Rightarrow (z, y) \in b \}$
- 2.  $a/b = \{\langle x, y \rangle \mid \forall z (y, z) \in b \Rightarrow (x, z) \in a\}$

One may illustrate composition and residuals in PRA and RRA via the following triangles:

Given a subset of definable operations in  $\mathbf{R}\mathbf{A}$   $\tau$ , we denote the class of subalgebras of the  $\tau$ -reducts by  $\mathbf{R}(\tau)$ . The algebras containing to this class are defined as restrictions of elements belonging to  $\mathbf{R}\mathbf{s}$  to operations of  $\tau$ . By  $\mathbf{Q}(\tau)$  we mean a quasivariety generated by  $R(\tau)$ . As in [12], we put  $\mathbf{Q}(\tau)$  as the closure of  $\mathbf{R}(\tau)$  under subalgebras and products assuming that  $\mathbf{R}(\tau)$  is already closed under ultraproducts.

## 2 The Finite Base Property

We recall the underlying definitions according to [9, Section 19]

**Definition 2.** Let  $\mathbf{K}$  be a class of algebras of a signature  $\Omega$ ,  $\mathbf{K}$  has the finite algebra property, if if any first-order  $\Omega$ -sentence that is true in all finite algebras in  $\mathbf{K}$  is true in every algebra in  $\mathbf{K}$ .

The finite base property is a version of the finite algebra property if  $\mathbf{K}$  is a class of representable algebras:

**Definition 3.** Let K be a class of representable algebras of a signature  $\Omega$ 

- 1. **K** has the finite base property if any first-order  $\Omega$ -sentence that is true in every algebra in **K** having a representation over a finite base set is valid in **K**.
- 2. **K** has the finite algebra on finite base property if any finite algebra in **K** has a representation with finite base.
- 3. **K** has the finite algebra property for equations/quasi-identites if any equation/quasi-identity that is true in all finite algebras is true in every algebra in **K**. The finite base property for equations/quasi-identites is defined similarly.

The following statements were shown in [3]. This lemma connects finite base property with finite algebra on finite base and finite algebra properties as follows:

**Lemma 1.** Let **K** be a class of representable  $\Omega$ -algebras:

- 1. If **K** has the finite algebra property, then it has the finite algebra and the finite base properties for equations/quasi-identites.
- 2. The finite algebra on finite base and the finite algebra properties implies the finite base property for **K**. The same holds for equations/quasi-identites.
- 3. If any representation of an infinite algebra has an infinite base, then the finite base property implies the finite algebra one for **K**.
- 4. Suppose  $\Omega$  is finite and any subalgebra of a representable algebra is representable on the same base. Then the finite base property implies the finite algebra on finite base property.

## 3 The Relation Residuated Semigroups Background

#### 3.1 The underlying definitions and results

A relation structure (**RS**) is an arbitrary algebra of the signature  $\Omega = \langle \cdot, \setminus, /, \leq \rangle$ , where  $\cdot, \setminus, /$  are binary function symbols and  $\leq$  is a binary relation symbol.

**Definition 4.** A residuated semigroup is an algebra  $S = \langle S, \cdot, \leqslant, \setminus, / \rangle$  such that  $\langle S, \cdot, \leqslant, \rangle$  is an ordered residuated semigroup **ORS** an the following equivalences hold for each  $a, b, c \in S$ :

$$b \leqslant a \backslash c \Leftrightarrow a \cdot b \leqslant c \Leftrightarrow a \leqslant c/b$$

It is clear that  $\mathbf{ORS}$  is a quasivariety and, thus [17], is closed under subalgebras, products, and ultraproducts, i. e.,  $\mathbf{ORS} = \mathbf{SPUp} \ \mathbf{ORS}$ .

**Definition 5.** Let A be a set of binary relations on some base set W such that  $R = \bigcup A$  is transitive and  $\{x,y \mid xRy\} = W$ . A relation residuated semigroup is an algebra  $\mathcal{A} = \langle A, ; , \backslash , /, \subseteq \rangle$  where for each  $r,s \in A$ 

- 1.  $r; s = \{\langle a, c \rangle \mid \exists b \in W \ (\langle a, b \rangle \in r \& \langle b, c \rangle \in s)\}$
- 2.  $r \setminus s = \{ \langle a, c \rangle \mid \forall b \in W \ (\langle b, a \rangle \in r \Rightarrow \langle b, c \rangle \in s) \}$
- 3.  $r/s = \{\langle a, c \rangle \mid \forall b \in W \ (\langle c, b \rangle \in s \Rightarrow \langle a, b \rangle \in r)\}$

Relation residuated semigroup are also called representable relativised relational structure (RRS).

Andréka and Mikulás proved the following representation theorem for **ORS** in [4] that implies relational completeness of the Lambek calculus, the logic of **ORS**:

**Theorem 1. ORS = IRRS**, where **IRRS** is a closure of **RRS** under isomorphic copies.

#### 3.2 The finite base property for RRS

**Definition 6.** A relativised representation

**Definition 7.** The standard translation

TODO: take a look at relativised representations and loosely guarded fragments in general TODO: realise whether it makes sense to use the technique similar to [9, Theorem 19.13] used for weakly associative algebras.

**Theorem 2.** Let A be a finite residuated semigroup and  $|A| < \omega$ , then A has a finite relativised representation.

**Theorem 3.** Let A be a finite representable residuated semigroup, then A is isomorphic to representable residuated semigroup a domain of which is finite.

**Theorem 4.** That might follow from the previous theorem, Theorem, and something else.

Corollary 1. The Lambek calculus has the fmp and the universal theory of IRRS is NP-complete.

The hypothetical plan is the following one:

- 1. Define properly relativised representation for residuated semigroups, that should look like ternary Kripke frames for the basic Lambek calculus or arrow logic.
- 2. Define the standard translation to such first-order relation structures. TODO: take a look at the loosely guarded fragment stuff.
- 3. Every finite residuated semigroup has a finite relativised representation.
- 4. If every  $\Pi_1$ -statement  $\varphi$  of the language of residuated semigroups that is valid in every residuated semingroup is valid in algebra having a finite relativised representation (one may use here Theorem 4 somehow), then  $\varphi$  is valid in **ORS** as well as in **IRRS**.
- 5. Every finite residuated semigroup should have a finite relativised representation.
- 6. Construct a finitely based relation residuated semigroup from that (an analogue of complex algebra or smth like that). This item is the most non-trivial one.
- 7. As a corollary, the first-order universal first-order theory of **IRRS** should be decidable and (it seems so) NP-complete (that should follow from the results in [22]).

## 4 Join-semilattice ordered semigroups

**Definition 8.** A join-semilattice ordered semigroup (**ASOS**) is an algebra  $S = \langle S, \cdot, \vee \rangle$  such that  $\langle S, \cdot \rangle$  is a semigroup,  $\langle S, \vee \rangle$  is a join-semilattice and the following equations hold for each  $a, b.c \in S$ :

1. 
$$a \cdot (b \vee c) = (a \cdot b) \vee (a \cdot c)$$

2. 
$$(a \lor b) \cdot c = (a \cdot c) \lor (b \cdot c)$$

This class is clearly a variety since **ASOS** has the equational definition so far as  $\vee$  is defined as an associative, idempotent, and commutative operation.

Let A be a set of binary relations on some base set W such that  $R = \cup A$  is transitive and  $\{x,y \mid xRy\} = W$  as in Definition 5. A relation join-semilattice ordered semigroup (**RJSOS**) is an algebra of binary relations  $\mathcal{A} = \langle A, ;, \cup \rangle$  such that ; is a relation composition as above and  $\cup$  is the set-theoretic union. It is known that the class of all representable join-semilattice ordered semigroups has no finite axiomatisation [1].

**Theorem 5.** The equational and quasiequational theories of  $R(;,\vee)$  is not finitely based.

*Proof.* TODO: use games and rainbow stuff
